**NEW QUESTION: 1**

Refer to the exhibit. A new subnet with 60 hosts has been added to the network. Which subnet address should this network use to provide enough usable addresses while wasting the fewest addresses?

- A. 192.168.1.56/26
- B. 192.168.1.64/27
- C. 192.168.1.56/27
- D. 192.168.1.64/26

**Answer: D**

Explanation:

A subnet with 60 host is  $2*2*2*2*2*2 = 64 - 2 == 62$

6 bits needed for hosts part. Therefore subnet bits are 2 bits (8-6) in fourth octet.

8bits+ 8bits+ 8bits + 2bits = /26

/26 bits subnet is 24bits + 11000000 = 24bits + 192

256 -192 = 64

0 - 63

Step 1: Add a new availability replica in asynchronous mode. Asynchronous-commit mode minimizes transaction latency on the secondary databases but allows them to lag behind the primary databases, making some data loss possible.

Incorrect: Add a new availability replica in synchronous mode. Synchronous-commit mode ensures that once a given secondary database is synchronized with the primary database, committed transactions are fully protected. This protection comes at the cost of increased transaction latency.

Step 2: Set Readable Secondary to Read-intent only.

For the secondary role, select a new value from the Readable secondary drop list, as follows: Read-intent only Only read-only connections are allowed to secondary databases of this replica. The secondary database(s) are all available for read access.

Step 3: Configure read-only routing.

Note: Read-only routing refers to the ability of SQL Server to route qualifying read-only connection requests to an available Always On readable secondary replica (that is, a replica that is configured to allow read-only workloads when running under the secondary role). To support read-only routing, the availability group must possess an availability group listener. Read-only clients must direct their connection requests to this listener, and the client's connection strings must specify the application intent as "read-only." That is, they must be read-intent connection requests.
